Abstract

Discovery and integration of data is important in many ecological studies, especially those that concern broad-scale ecological questions. Data discovery and integration is often a difficult and time-consuming task for researchers, which is due in part to the use of informal, ambiguous, and sometimes inconsistent terms for describing data content. Ontologies offer a solution to this problem by providing consistent definitions of ecological concepts that in turn can be used to annotate, relate, and search for data sets. However, unlike in molecular biology or biomedicine, few ontology development efforts exist within ecology. Ontology development often requires considerable expertise in ontology languages and development tools, which is often a barrier for ontology creation in ecology. In this paper we describe an approach for ontology creation that allows ecologists to use common spreadsheet tools to describe different aspects of an ontology. We present conventions for creating, relating, and constraining concepts through spreadsheets, and provide software tools for converting these ontologies into equivalent OWL-DL representations. We also consider inverse translations, i.e., to convert ontologies represented using OWL-DL into our spreadsheet format. Our approach allows large lists of terms to be easily related and organized into concept hierarchies, and generally provides a more intuitive and natural interface for ontology development by ecologists.

1. Introduction

Within the fields of molecular biology and biomedicine considerable effort has gone into developing ontologies for improving data discovery and integration Ashburner, *et al* [2000], Bard and Rhee [2004]. While similar benefits can be obtained for ecological data, far fewer efforts exist to develop broad and consistent terminologies within ecology Madin et al. [2008], Parr and Cummings [2004]. The use of formal ontologies can significantly enhance metadata descriptions of ecological data. For instance, annotating data with ontology terms can both help users interpret data as well as enable advanced capabilities for data discovery and integration, e.g., by exploiting subsumption and part-of hierarchies as well as more formal constraints such as cardinality restrictions on properties and term equivalence Madin et al. [2008].

Efforts to engage scientists in the development of ontologies typically leverage the W3C Web Ontology Language (OWL) Smith et al. [2004] as a standard XML syntax for representing and sharing ontologies. A key advantage of OWL is that it is supported by a wide range of generic tools, including editors Knublauch et al. [2004], Kalyanpur et al. [2005], reasoning systems Sirin et al. [2007], Tsarkov and Horrocks [2006], query languages Prudhom-

meaux and Seaborne [2008], Motik et al. [2005], and storage technologies Carroll et al. [2004], Broekstra et al. [2002]. Most of these tools, however, are primarily targeted at experts in knowledge engineering and software development familiar with the underlying description logic semantics of OWL-DL Grau et al. [2008]. This is especially true with ontology editors (such as Protege, SWOOP, etc.), which allow for very detailed ontology specifications, but at the same time require considerable understanding of the underlying ontology formalisms and syntax. We see the lack of suitable ontology editing tools for scientists without expertise in knowledge representation as one of the major barriers for more wide-scale adoption of ontologies in ecology.

This paper presents a novel approach for ontology creation that aims at being more intuitive for ecologists and that can be used to rapidly construct large ontologies for describing scientific data. Our approach is to allow scientists to use common spreadsheet-based tools to describe, in an intuitive way, different aspects of an ontology, and then to take these descriptions and convert them into full-fledged OWL ontologies using a software application called owlifier. An owlifier spreadsheet consists of a set of *blocks* that have a predefined template structure for users to fill in. Each non-empty row in an owlifier table constitutes a block. Each block defines different aspects of an ontology including ontology classes, subclasses, synonyms, and

^{*}Corresponding author

properties. We also provide blocks for plain-text descriptions of classes and properties, and for referencing one or more existing ontologies (e.g., to extend an existing ontology or to define ontology articulations). Blocks can be sparse (inheriting from previous blocks), which can further simplify the creation of large ontologies.

While not as expressive as OWL-DL, our approach can produce ontology structures that are essential for improved data discovery and integration Madin et al. [2007]. Just as important, because spreadsheet tools are frequently used by ecologists to store and analyze data, *owlifier* can provide ecologists with a familiar and accessible user interface for ontology creation. This approach also leverages the ability of spreadsheet tools to organize and manipulate tabular data, e.g., allowing users to rapidly construct class hierarchies from long lists of keywords. In this way, an ecologist can easily construct (or import) a set of terms, and then incrementally organize these into class hierarchies, properties, and constraints. In initial experiments with ecologists and evolutionary biologists studying trait data, we found that *owlifier* enabled them to quickly and easily comprehend and construct relatively complex and meaningful ontologies.

The rest of this paper is organized as follows. In Section 2 we describe the basic syntax and semantics of *owlifier*. We define blocks that support a large subset of OWL-DL and that also generally follow the ontology creation guidelines defined in Rector et al. [2004]. We also simplify certain aspects of ontology creation using OWL-DL, e.g., by assuming classes are disjoint by default (unless specified otherwise) Rector et al. [2004]. In Section 3 we describe additional characteristics of *owlifier* and discuss issues with respect to classification and reasoning. In Section 4 we briefly describe the *owlifier* implementation, and conclude in Section 5 with related and future work. In general, the goal of *owlifier* is not to support all constructs in OWL-DL, but instead to provide a higher-level ontology syntax (via spreadsheet blocks) that is easy for ecologists to use and understand while also providing the necessary constructs for developing typical ecological ontologies. By compiling *owlifier* to OWL-DL, we also allow for experts to refine and extend the ontology using more advanced ontology editing tools if necessary (cf. Figure 1).

2. The Syntax and Semantics of Owlifier

As described above, an *owlifier* table defines an OWL-DL Smith et al. [2004] ontology through a set of *blocks* representing one or more ontology definitions. Each non-empty row in an *owlifier* table corresponds to a block. The type of the block is given in the first column of the row. We assume that if any properties or classes used in a block are not imported from another ontology, then they are to be added to the ontology being specified by the *owlifier* table (i.e., the “current” ontology). In general, we name blocks according to the terms used in Bowers et al. [2008], Madin

et al. [2007] as opposed to the names used for corresponding constructs in OWL-DL. This choice of block names helps to simplify terminology (e.g., we use “relation” below instead of “object property”), allows *owlifier* to easily generate ontologies that extend the observational model of Bowers et al. [2008], Madin et al. [2007], and avoids confusion with established terms commonly used within ecology (e.g., “class”).

Import Blocks. Import blocks assign namespace labels to external ontologies. Each external ontology is imported into the current ontology. We refer to the ontologies of import blocks as *imported ontologies*. Using import blocks, classes and properties of imported ontologies can be used within other blocks of an *owlifier* table. Rows containing import blocks take the form

import	n	u
--------	-----	-----

where n is a namespace label and u is an OWL ontology URI. Classes and properties from imported ontologies are referenced by prefixing the namespace label n to the corresponding class or property name in the normal way. As an example, the following block imports the SWEET “Earth Realm” ontology Raskin

```
import sweet http://sweet.jpl.nasa.gov/ontology/earthrealm.owl
```

With this import block the class denoting Marine Ecosystems (a class defined in the SWEET ontology) can be referred to from within an *owlifier* table using the expression `sweet:MarineEcosystem`. Because this class refers to a class in another ontology, we refer to it as an *imported class*.

Entity Blocks. Entity blocks are the primary blocks used to define ontologies. An entity block introduces new OWL classes and specifies subclass relationships. Imported classes may also be used within entity blocks by prefixing class names with namespace labels (as described above). Rows containing entity blocks take the form

entity	c_1	c_2	\dots	c_n
--------	-------	-------	---------	-------

 $(n \geq 1)$

where each class c_i is asserted in the current ontology to subsume c_{i+1} , for $1 \leq i < n$. That is, each c_i in an entity block induces the description logic axiom $c_{i+1} \sqsubseteq c_i$. If both c_i and c_{i+1} are imported classes, we say that the block defines an “articulation” (i.e., mapping) between the two classes. The following entity block defines a simple subclass hierarchy.

```
entity PhysicalFeature AquaticPhysicalFeature River
```

This block states that Physical Feature, Aquatic Physical Feature, and River are classes; River is a subclass of Aquatic Physical Feature; and Aquatic Physical Feature is a subclass of Physical Feature. The following entity block introduces a new class via an imported class.

```
entity sweet:MarineEcosystem IntertidalEcosystem
```

This block states that Intertidal Ecosystem is a subclass of the Marine Ecosystem class imported from the SWEET ontology. Similarly, assuming “marine” denotes an existing ontology of marine ecosystem concepts, the following block defines a simple class articulation.

entity sweet:MarineEcosystem marine:DeepSeaEcosystem

This block states that the Deep Sea Ecosystem class of the marine ontology is a subclass of the Marine Ecosystem class of the SWEET ontology (thus defining a mapping between these two ontologies).

Synonym Blocks. Synonym blocks define equivalence relationships between ontology classes. Rows containing synonym blocks take the form

synonym	c_1	c_2	\dots	c_n
---------	-------	-------	---------	-------

 $(n \geq 2)$

where each class c_i is equivalent to class c_{i+1} in the current ontology, for $1 \leq i < n$. That is, each c_i in a synonym block induces a description logic axiom of the form $c_i \equiv c_{i+1}$. The following synonym block creates a simple equivalence relationship.

synonym Maize Corn

This block states that the Maize and Corn classes are synonyms (equivalent classes). Similar to entity blocks, synonym blocks often contain imported classes for extending existing ontologies or defining ontology mappings.

Overlap Blocks. Except in certain situations (described further in Section 3), classes are generally assumed to be disjoint in owlifier. Overlap blocks explicitly relax this assumption by stating that a given set of classes may have overlapping instances. Rows containing overlap blocks take the form

overlap	c_1	c_2	\dots	c_n
---------	-------	-------	---------	-------

 $(n \geq 2)$

where each class c_i is allowed to share instances with each class c_j , for $1 \leq i, j \leq n$. That is, a given c_i and c_j in an overlap block are not defined to be disjoint classes in the current ontology. As an example, consider the following entity blocks that define the classes Estuary, Lagoon, and Marsh as subclasses of Ecological Habitats.

entity EcologicalHabitat Estuary
entity EcologicalHabitat Lagoon
entity EcologicalHabitat Marsh

Given only these blocks, owlifier treats Estuary, Lagoon, and Marsh as disjoint classes. To relax this assumption and allow, e.g., types of Lagoons to also be types of Estuaries, we explicitly add the following overlap block

overlap Estuary Lagoon

In general, overlap blocks are rarely used but provide a mechanism to override the default behavior of owlifier in asserting disjoint classes.

Relationship Blocks. Relationship blocks define *required* class object properties. An object property within OWL is a property defined between two class instances. Rows containing relationship blocks take the form

relationship	p	c_1	c_2	\dots	c_n
--------------	-----	-------	-------	---------	-------

 $(n \geq 2)$

where p is an object property and each c is a class. For every class c_i , the relationship block induces the description logic axiom $c_i \sqsubseteq \exists p.c_{i+1}$ stating that each instance of c_i is p -related to some instance of c_{i+1} , for $1 \leq i < n$. For example, the following block states that instances of the class California Voles live in Grassy Areas.

relationship livesIn CaliforniaVole GrassyArea

In some cases, a particular property can apply to a sequence of classes, and for convenience, each such class can be specified in owlifier using a single block. For example, consider the following block.

relationship directlyBelow Hypolimnion Thermocline Epilimnion

This block states that, e.g., within a thermally stratified lake, the Hypolimnion layer is directly below the Thermocline layer, and the Thermocline layer is directly below the Epilimnion layer.

Transitive Blocks. Transitive blocks are special cases of relationship blocks where the object property is asserted to be transitive. That is, if a property p is declared to be transitive, and p relates an individual x to an individual y and y to an individual z , then p is assumed to also relate x to z . Rows containing transitive blocks take the form

transitive	p	c_1	c_2	\dots	c_n
------------	-----	-------	-------	---------	-------

 $(n \geq 2)$

where p is an object property and each c is a class. The following block is a simple example of a transitive relationship definition.

transitive hasPart Body Head Eye Retina

This block states that every instance of the class Body has a Head as a part, every instance of the class Head has an Eye as a part, and every instance of the class Eye has a Retina as a part. Moreover, because the **hasPart** property above is defined to be transitive, it is possible to infer that every instance of Body also has an Eye and a Retina as a part through the inherited relationship restrictions $\text{Body} \sqsubseteq \exists \text{hasPart.Head}$, $\text{Head} \sqsubseteq \exists \text{hasPart.Eye}$, and $\text{Eye} \sqsubseteq \exists \text{hasPart.Retina}$.

Cardinality Blocks. Cardinality blocks are also similar to relationship blocks. We consider three types of cardinality blocks for defining minimum, maximum, and exact cardinality restrictions. Rows containing minimum blocks take the form

min	p	m	c_1	c_2	\dots	c_n
-----	-----	-----	-------	-------	---------	-------

 $(n \geq 2)$

where m is the minimum number of properties p that instances of class c_i must have to instances of concept c_{i+1} , for $1 \leq i < n$. For each class c_i , a minimum cardinality block induces the description logic axiom $c_i \sqsubseteq (\leq m) p.c_{i+1}$ stating that each instance of c_i must be p -related to at least m unique instances of c_{i+1} . The following two blocks demonstrate simple minimum cardinality constraints.

min hasPart 1 Body Head Nose
min hasPart 2 Head Eye

The first block states that instances of the class Body have at least one Head as a part, which in turn have at least one Nose as a part.¹ The second block states that instances of the class Head have at least two Eyes as parts.

Rows containing maximum blocks take the form

max	p	m	c_1	c_2	\dots	c_n	$(n \geq 2)$
-----	-----	-----	-------	-------	---------	-------	--------------

where m is the maximum number of properties p that instances of concept c_i may have to instances of concept c_{i+1} , for $1 \leq i < n$. For each class c_i , a maximum cardinality block induces the description logic axiom $c_i \sqsubseteq (\geq m) p.c_{i+1}$ stating that each instance of c_i may be p -related to at most m unique instances of c_{i+1} . The following two blocks demonstrate simple maximum cardinality constraints.

max hasPart 1 Body Head Nose
max hasPart 2 Head Eye

The first block states that instances of the class Body have at most one Head as a part, which in turn has at most one Nose as a part. The second block states that instances of the class Head have at most two Eyes as parts.

Rows containing exact blocks take the form

exact	p	m	c_1	c_2	\dots	c_n	$(n \geq 2)$
-------	-----	-----	-------	-------	---------	-------	--------------

where m is the number of properties p that instances of concept c_i must have to instances of concept c_{i+1} , for $1 \leq i < n$. For each class c_i , an exact block induces the description logic axiom $c_i \sqsubseteq (= m) p.c_{i+1}$ stating that each instance of c_i must be p -related to m unique instances of c_{i+1} .

Inverse Blocks. Inverse blocks state that two object properties are inverses of each other. If p_1 and p_2 are defined to be inverse properties, whenever p_1 relates an individual x to an individual y then p_2 (as the inverse of p_1) is assumed to relate y to x . Rows containing inverse blocks take the form

inverse	p_1	p_2
---------	-------	-------

¹Cardinality restrictions ensuring participation to at least one property are typically not given through minimum cardinality blocks since they are also implied by relationship blocks.

where p_1 and p_2 are object properties. A common example of inverse properties are **hasPart** and **partOf**, i.e., if an individual x has an individual y as a part, then y is by definition a part of x .

Sufficient Blocks. Sufficient blocks are similar to synonym blocks in that they state equivalences between classes. A sufficient block serves as a modifier to entity blocks, relationship blocks (including transitive blocks), and cardinality blocks, modifying the associated description logic axioms by using equivalence (\equiv) in place of subclass (\sqsubseteq). For example the block

sufficient relationship hasPart Mammal Hair

induces the description logic axiom $\text{Mammal} \equiv \exists \text{hasPart.Hair}$ stating that *any* individual that has Hair as a part is a Mammal. Additionally, we allow relationship blocks within a sufficient block to be extended with **not** to state that the absence of the property is a defining characteristic of the class. For example the following blocks

sufficient entity Mammal Eutheria
sufficient relationship not hasPart Eutheria EpipubicBone

induces the axiom $\text{Eutheria} \equiv \text{Mammal} \sqcap \neg \exists \text{hasPart.EpipubicBone}$ stating that any Mammal that does not have an Epipubic Bone as a part is a Eutheria. Note also that multiple sufficient blocks for a particular class result in a single axiom in which each constraint (i.e., class constructor) is combined via intersection (\sqcap).

Comment Blocks. Comment blocks provide a mechanism to add plain-text comments to owlifier tables. A description block attaches a plain-text comment to classes and properties. Rows containing description blocks take the form

description	c or p	s
-------------	------------	-----

where the string s is associated as a comment to the class c or property p . A note block attaches comments to the current ontology. Rows containing note blocks take the form

note	s
------	-----

where s is a comment string.

3. Additional Features of Owlifier

Here we briefly describe some of the additional features of owlifier, specifically focusing on the use of disjoint classes, owlifier reasoning, and additional block syntax.

3.1. Disjoint Class Inference

OWL is based on the open world assumption, which can lead to a number of ontology development “pitfalls” for those new to the language Smith et al. [2004], Rector

et al. [2004]. One example is in the creation of disjoint classes. In particular, unless explicitly asserted, distinct classes within an OWL-DL ontology are not assumed to be disjoint. However, in many ontologies a large number of classes are typically defined as being disjoint (e.g., sibling classes), and stating these disjoint constraints is often time consuming since each pair of classes must be given an explicit disjoint assertion. Editors such as Protege Knublauch et al. [2004] provide shortcuts via the user interface to create specific sets of disjoint assertions, e.g., by allowing a user to define all children of a particular class as disjoint. In general, however, many users expect such classes to be disjoint by default Rector et al. [2004] and this expectation often leads to modeling errors.

Alternatively, the default assumption in *owlifier* is that distinct classes are disjoint. Specifically, as an *owlifier* table is converted to an OWL-DL ontology, the system analyzes the class hierarchy structure and identifies pairs of classes that are: (1) not related via subclass relations (either direct or indirect subclasses); (2) not defined as synonyms; and (3) not explicitly defined to overlap via an overlap block. Each such pair of classes is then asserted by *owlifier* in the resulting ontology as being disjoint. As described in Rector et al. [2004], undeclared disjoint classes are a common problem in ontology development using OWL-DL and often limit the utility of reasoning systems (by limiting the inferences that can be obtained). The approach employed in *owlifier* for handling disjoint classes makes the common expectations of users the default case, which in general should lead to a more intuitive ontology editing environment and an overall fewer number of modeling mistakes.

3.2. Reasoning in Owlifier

Blocks in *owlifier* are unambiguous, i.e., for every *owlifier* block (or set of blocks in the case of sufficient blocks) there is a well-defined set of corresponding OWL-DL axioms. This property is important because it implies that reasoning can be performed over ontologies defined in *owlifier* using standard OWL-DL reasoners. We use this capability in our current *owlifier* implementation (described further in Section 4) to verify ontologies defined using *owlifier* and report possible errors to users.

In general, new axioms are inferred from an *owlifier* ontology primarily from the use of synonym blocks, sufficient blocks, and transitive blocks (whose inferences are described in the previous section). For instance, let A , B , and C be classes and P be an object property. From an axiom $A \equiv B$ generated from a synonym block, and an axiom $B \sqsubseteq \exists P.C$ generated from a relationship block, the axiom $A \sqsubseteq \exists P.C$ would be inferred. Thus, the axioms of a particular class are “inherited” by all of the synonyms of the class. Similarly, from an axiom $A \equiv \exists P.C$ generated from a sufficient block, and an axiom $B \sqsubseteq \exists P.C$ generated from a relationship block, the axiom $B \sqsubseteq A$ would be inferred. For both the case of synonym and sufficient blocks, the use of equivalence permits a number of additional inferences to be made via an OWL-DL reasoner.

As described in Rector et al. [2004] additional reasoning can occur within OWL-DL ontologies when domain and range axioms are provided (as well as, e.g., property closure axioms). We explicitly do not consider these constraints in the current version of *owlifier* because they also often result in modeling errors for inexperienced OWL-DL users Rector et al. [2004]. Instead, we adopt the approach of more traditional description logics, which do not have explicit domain and range axioms. Although not currently supported in *owlifier*, domain and range constraints as well as property closure axioms can be inferred from given relationship blocks.

3.3. Sparse Blocks

To help simplify the creation of class hierarchies and property sequences (including transitive, cardinality, and sufficient blocks), we allow for “sparse” blocks that inherit missing information from their closest preceding block. For instance the following entity blocks

```
entity EcologicalHabitat Estuary Bay
entity EcologicalHabitat Estuary Fjord
entity EcologicalHabitat Marsh TidalMarsh
entity EcologicalHabitat Marsh SaltMarsh
```

can be equivalently represented in *owlifier* using the following sparse blocks.

```
entity EcologicalHabitat Estuary Bay
                                     Fjord
Marsh TidalMarsh
                                     SaltMarsh
```

In general, the use of sparse blocks simplifies ontology creation by not requiring users to enter every redundant field explicitly, which in turn can simplify the overall layout of the ontology within a spreadsheet. Additionally, *owlifier* does not place constraints on the order of blocks within a spreadsheet. Classes also do not need to be explicitly defined within an entity block, e.g., classes without corresponding entity blocks can be introduced simply through synonym and relationship blocks. This typically occurs when a particular class does not participate as a subclass or superclass of another class in the current ontology. Taken together, these approaches allow users to enter minimal information by limiting redundancy and by supporting a range of inferences, while at the same time reducing the causes of many errors commonly made in ontology development by non-experts.

4. The Owlifier Implementation

Figure 1 shows the general architecture of the *owlifier* application. A scientist or researcher first creates a spreadsheet containing a set of ontology definitions using *owlifier* conventions. The spreadsheet is then exported as a plain-text file containing the *owlifier* table, e.g., using a CSV or tab-delimited format. The *owlifier* table is then sent to

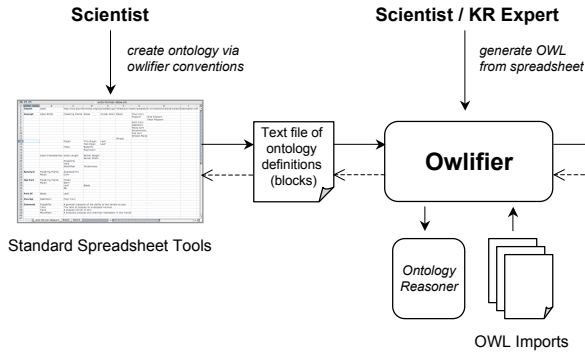

Figure 1: The basic owlifier application and relation to other technologies.

the owlifier application, which performs a number of steps that include: (i) parsing the file; (ii) generating the corresponding OWL-DL representation (e.g., in the current implementation, the Jena API is used Carroll et al. [2004]); (iii) validating the ontology and ensuring it is consistent via an OWL-DL reasoner (e.g., the current implementation uses Pellet Sirin et al. [2007]); and (iv) outputting the corresponding OWL-DL file. The resulting OWL file can then be refined and extended via existing OWL tools (e.g., Protege or SWOOP). It is possible that the refined ontology is converted back to a corresponding owlifier representation (shown using dashed lines in Figure 1). While straightforward to perform, this last conversion is not information preserving since not all OWL-DL constructs are represented through owlifier blocks.

The current implementation of the owlifier application is written in Java and supports a subset of the blocks defined in Section 2. In particular, we are currently extending owlifier to support cardinality and sufficient blocks as well as to perform the above conversion from OWL-DL files to corresponding owlifier blocks. As noted above, the current implementation, although it does not support all of the blocks defined here, is being used within a project focused on supporting trait data and many of the extensions outlined here are based on these experiences. In addition, owlifier has been used to construct term hierarchies from large sets of keywords (harvested from existing metadata documents) as well as to define articulations between existing ontologies and the observation ontology defined in Madin et al. [2007].

5. Conclusion

This paper presents a new approach for developing ontologies to address barriers in ontology development and adoption by ecologists. Our approach allows scientists to use familiar spreadsheet software (e.g., frequently used by ecologists for storing and analyzing data) to create ontologies by filling in a set of templates, or blocks, that generate OWL-DL class hierarchies, properties, and constraints via the owlifier application. This approach can provide a

more intuitive and accessible ontology editing environment for ecologists, especially compared to existing OWL-based tools that require considerable expertise in the underlying logic formalisms.

Protege provides a variety of ontology editing plugins, including a simple interface for text-based editing of class hierarchies. In Kola and Rector [2007], an approach is described for importing spreadsheet-based ontology descriptions into Protege. However, this approach aims at supporting *ad-hoc* spreadsheet structures by providing an intermediate interface for mapping these structures into ontology axioms. This approach is similar to others (e.g., Han et al. [2008], Bizer [2003], An et al. [2006]) for defining mappings from relational data to RDF and OWL ontology class and instance data. To the best of our knowledge, however, our approach is the first to consider a detailed set of templates that can support a large subset of existing OWL constructs. In addition, we define a number of shortcuts for creating owlifier tables, including sparse blocks and default semantics (e.g., disjoint classes, which is a form of global taxonomic constraint defined in Thau and Ludäscher [2007]) that further simplify ontology creation for end users.

As future work, we intend to extend our current owlifier implementation to support the full set of blocks defined above. We also intend to explore approaches to fully support conversions between owlifier tables and OWL-DL ontologies. In particular, we want to extend owlifier to re-apply changes made by knowledge representation experts that previously modified the OWL-DL ontology generated by owlifier. For instance, if an OWL-DL ontology generated from an owlifier table is refined and extended by a knowledge representation expert, then converted back into an owlifier ontology that is further edited and extended by a scientist, and then converted again into an OWL-DL ontology, we want to maintain (i.e., re-apply) the original extensions and edits created by the knowledge representation expert that are still relevant. We are also developing extensions to owlifier to support conversion into the observation ontology framework presented in Bowers et al. [2008] and intend to perform additional testing and evaluation of the owlifier approach with ecologists.
